An Assessment of the Economic Impacts of the Rosemont Copper Project on the Economies of the Cochise/Pima/Santa Cruz Counties Study Area, the State of Arizona, and the United States

Executive Summary

This report summarizes the results of an economic impact analysis of the Rosemont Copper Project, an open-pit mining operation to be developed on a 15,000 acre site in Pima County about 30 miles southeast of Tucson. The analysis employed the REMI PI+ regional economic forecasting model to estimate the economic impacts of the Project for the Cochise/Pima County/Santa Cruz Counties study area, for the State of Arizona, and for the United States.

Cochise/Pima/Santa Cruz Counties

Construction Phase

- Construction of the Project will generate an average annual increase of \$96 million (all
 dollar-denominated figures refer to 2008\$) in economic activity in the study area
 (measured in terms of demand for goods and services from local suppliers) over a fouryear engineering/construction period.
- The engineering/construction phase will provide a total of 3,600 person-years of employment for local workers.
- Wages and salaries and non-labor income (dividends, interest, rent, proprietors' income, and net profits) produced by the economic activity associated with the engineering/construction phase will provide an average of \$38 million per year in additional income to area residents.
- The engineering/construction phase will generate almost \$5 million per year in revenues for local governments in the study area.

 Over the entire engineering/construction period, impacts will total \$385 million in additional demand for goods and services from suppliers in the study area, \$245 million in gross regional product, \$152 million in personal income, and \$18 million in local government revenues.

Production/Post-Production Phase

- Production activities will generate an average annual increase of \$701 million per year in economic activity (measured in terms of incremental regional output) within the study area over a 20-year production period.
- Mine and mill operations will employ an average of 406 workers with peak employment of 444 – and will support an average of 1,700 other jobs – a total of approximately 2,100 additional jobs for area residents.
- Wages and salaries and non-labor income produced by the economic activity will provide an annual average of \$143 million in additional income to area residents.
- Production activities will generate an average of \$19 million per year in incremental revenues for local governments in the study area.
- Over the entire expected production/post-production period, the overall impacts will be \$15 billion in additional output, \$8 billion in gross regional product, \$3 billion in personal income, and \$404 million in local government revenues.
- The Rosemont Copper Project will have lasting positive effects on the economy of the study area. Permanent changes to the regional economy would occur as a result of the increased levels of economic activity associated with the development and operation of the Rosemont mine. These changes will result in residual economic impacts in the Cochise/Pima/Santa Cruz Counties area that will persist after the end of the Project. The forecast results indicate that the level of economic activity would be \$52 million per year higher, the area residents' income \$68 million per year higher, employment more than 300 higher, and local government revenues \$2 million per year more than if the Rosemont Copper Project never existed.

The State of Arizona

Construction Phase

- Construction of the Project will generate an average annual increase of \$122 million in economic activity in the state (measured in terms of demand for goods and services from Arizona suppliers) over a four-year engineering/construction period.
- The engineering/construction phase will provide a total of 3,900 person-years of employment for Arizona workers.
- Wages and salaries and non-labor income resulting from the economic activity associated with the engineering/construction phase will provide an average of \$45 million per year in additional income to Arizona residents.
- The engineering/construction phase will generate almost \$6 million per year in revenues during the engineering/construction period for state government.
- Over the entire engineering/construction period, impacts will total \$489 million in additional demand for goods and services from Arizona suppliers, \$317 million in gross regional product, \$182 million in personal income, and \$23 million in state government revenues.

Production/Post-Production Phase

- Production activities will generate an average annual increase of \$907 million per year in economic activity (measured in terms of incremental regional output) in the state over a 20-year production period.
- Mine and mill operations will support an average of 2,900 additional jobs for Arizona workers.
- Wages and salaries and non-labor income produced by the economic activity will provide an annual average of \$218 million in additional income for Arizona residents.
- Production activities will generate an average of \$32 million per year in incremental state government revenues.

- Over the entire expected production/post-production period, the overall impacts will be \$19 billion in additional output, \$11 billion in gross regional product, \$5 billion in personal income, and \$681 million in state government revenues.
- The Rosemont Copper Project will have lasting positive effects on the Arizona economy. Permanent changes to the state's economy would occur as a result of the increased levels of economic activity associated with the development and operation of the Rosemont mine. These changes will result in residual economic impacts in the state after the end of the Project. The forecast results indicate that the level of economic activity would be \$111 million per year higher, state residents' income \$96 million per year higher, employment 500 higher, and state government revenues \$4 million per year higher than if the Rosemont Copper Project never existed.

The United States

Construction Phase

- Construction of the Project will generate an average annual increase of \$568 million in economic activity in the nation (measured in terms of demand for goods and services) over a four-year engineering/construction period.
- The engineering/construction phase will provide a total of 11,600 person-years of employment for U.S. workers.
- Wages and salaries and non-labor income associated with the engineering/construction
 phase will provide an average of \$167 million per year in additional income to U.S.
 residents.
- The engineering/construction phase will generate \$53 million per year in additional revenues during the engineering/construction period for the federal government.
- Over the entire engineering/construction period, the impacts will total \$2.3 billion in additional demand for goods and services, \$1.2 million in gross domestic product, \$668 million in personal income, and \$210 million in federal government revenues.

Production/Post-Production Phase

- Production activities will generate an average annual increase of \$1.3 billion per year in economic activity in the nation (measured in terms of incremental output) over a 20-year production period.
- Mine and mill operations will support a total of 4,500 additional jobs for U.S. residents.
- Wages and salaries and non-labor income produced by the economic activity will provide an annual average of \$387 million in additional income to U.S. residents.
- Production activities will generate an average of \$128 million per year in incremental revenues for the federal government.
- Over the entire expected production/post-production period, the overall impacts will be \$27 billion in additional output, \$15 billion in gross domestic product, \$8 billion in personal income, and \$3 billion in federal government revenues.

THE ROSEMONT COPPER PROJECT

1. INTRODUCTION

This report summarizes the results of an economic impact analysis of the Rosemont Copper Project, an open-pit mining operation to be developed on a 15,000 acre site in Pima County about 30 miles southeast of Tucson. The analysis employed the REMI PI+ regional economic forecasting model to estimate the economic impacts of the Project for the Cochise/Pima County/Santa Cruz Counties study area, for the State of Arizona, and for the United States.

At prices of \$1.75/lb. for copper, \$15.00/lb. for molybdenum, and \$10.00/ounce for silver, combined proven and probable sulfide mineral reserves total nearly 546 million tons grading 0.45 percent copper, 0.015 percent molybdenum, and 0.12 ounces/ton silver. Proven and probable oxide mineral reserves total about 70 million tons grading 0.17 percent copper. Contained metal in the sulfide mineral reserves (proven and probable) is estimated to be 4.9 billion pounds of copper, 161 million pounds of molybdenum, and 65 million ounces of silver. Contained metal in the proven and probable oxide mineral reserves is estimated to be 241 million pounds of copper. The mining operation is projected to produce more than 200 million pounds of copper per year. In addition to copper, it is also projected to produce an average of 4.7 million pounds of molybdenum and 2.7 million ounces of silver per year (M3 Engineering and Technology Corp.).

The total cost of developing the site for mining and construction of the processing facilities will be \$897 million (2008\$). When in operation, employment will average 406 per year, and total annual production costs will average \$301 million per year during the 20-year production period (M3 Engineering and Technology Corp.).

1.1 Summary of the Results: Engineering/Construction Phase

The results of the economic impact analysis indicate that the engineering/construction phase will generate an average annual increase of \$96 million in economic activity in the three-county study area (measured in terms of demand for goods and services from local suppliers) and will provide a total of 3,600 person-years of employment for local workers during a four-year engineering/construction period. The jobs and non-labor income (dividends, interest, rent, proprietors' income, and net profits) produced by the economic activity will also provide an average of \$38 million per year in additional income to area residents and \$5 million per year in incremental revenues to local governments in the study area. Over the entire engineering/construction period, impacts will total \$385 million in additional demand for goods and services, \$245 million in gross regional product, \$152 million in personal income, and \$18 million in local government revenues.

For the State of Arizona, the economic impact analysis estimates that the engineering/construction phase will generate an average annual increase of \$122 million in economic activity in the state (measured in terms of demand for goods and services from Arizona suppliers) and will provide a total of 3,900 person-years of employment for Arizona workers during a four-year engineering/construction period. The jobs and non-labor income resulting from the economic activity will also provide an average of \$45 million per year in additional income to state residents and \$6 million per year in incremental state government revenues. Over the entire engineering/construction period, the impacts will total \$489 million in additional demand for goods and services from Arizona suppliers, \$317 million in gross regional product, \$182 million in personal income, and \$23 million in state government revenues.

For the U.S. economy, the engineering/construction phase will generate an average annual increase of \$568 million in economic activity in the nation and will provide a total of 11,600 person-years of employment for U.S. workers during a four-year engineering/construction period. The jobs and non-labor income produced by the economic activity will also provide an average of \$167 million per year in additional income to U.S. residents and \$53 million per year

in incremental revenues to the federal government. Over the entire engineering/construction period, impacts will total \$2.3 billion in additional demand for goods and services, \$1.2 billion in gross domestic product, \$668 million in personal income, and \$210 million in federal government revenues.

1.2 Summary of Results: Production/Post-Production Phase

The productive life of the Rosemont Copper Project is projected to be 20⁺ years. Based on the cost analysis in the feasibility study, the total costs associated with the production/post-production phase of the Project, including reclamation and costs related to closure of the mine will total over \$6 billion.

For the three-county study area, production activities will generate an average annual increase of \$701 million in economic activity (measured in terms of incremental regional output) and will support an average of 2,100 jobs for residents of the study area. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$143 million per year in additional income to area residents and \$19 million per year in incremental revenues to local governments in the region. Over the entire expected life of the Project, the overall impacts will be \$15 billion in additional output, \$8 billion in gross regional product, \$3 billion in personal income, and \$404 million in local government revenues.

For the State of Arizona, production activities will generate an average annual increase of \$907 million in economic activity and will support an average of 2,900 jobs for Arizona workers. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$218 million per year in additional income for state residents and \$32 million per year in incremental state government revenues. Over the entire expected life of the Project, the overall impacts will be \$19 billion in additional output, \$11 billion in gross regional product, \$5 billion in personal income, and \$681 million in state government revenues.

For the nation, production activities will generate an average annual increase of \$1.3 billion in economic activity and will support an average of 4,500 jobs for U.S. residents. The wages and

salaries and non-labor income produced by the economic activity will provide an average of \$387 million per year in additional income to U.S. residents and \$128 million per year in incremental federal government revenues. Over the entire expected life of the Project, overall impacts will be \$27 billion in additional output, \$15 billion in gross domestic product, \$8 billion in personal income, and \$3 billion in federal government revenues.

1.3 Comparison of Results with the Previous Analysis Based on a Pima/Santa Cruz Counties Study Area

All three parts of the economic impact analysis were prepared using the latest version of the REMI regional economic forecasting model. The Seidman Institute previously conducted a similar analysis of the economic impact of the Rosemont Copper Project based on a two-county study area comprised of Pima and Santa Cruz Counties (Seidman Institute 2009). That study did not include impact analyses for the state or for the nation. The earlier analysis employed a different version of the REMI model.

As a consequence of using the new version of the REMI model, the results for the three-county study area are not consistent with the previous estimates reported for the two-county study area. The estimated impacts for the engineering/construction phase are all substantially higher than the numbers reported in the previous study. For the production/post production phase, the employment, income-related, and government revenue numbers are higher, while output and gross regional product are somewhat lower than the earlier estimates.

Regional Economic Models Inc., the builder of the REMI model, has been in business for nearly 30 years and has a policy of continually updating their economic impact models based on the latest available data and advances in economic analysis and econometric methods. The model used for this analysis incorporates many changes to the previous version – including changes to both individual equations and to its overall structure. The parameters in the model have been re-estimated using a modified and updated dataset that included data through 2007. In addition, the economic forecasts incorporated into the new model were updated to reflect more recent views on future economic trends. The sum of these changes has resulted in somewhat

different results compared with the previous analysis. The fact that the numbers are different should be interpreted in that context rather than in terms of which numbers are "right." The results of the current analysis should be taken as reasonable estimates of the economic impact of the Rosemont Copper Project produced by a state-of-the-art regional forecasting model based on the current state of the local, state, and national economies.

2. Economic/Financial Overview

The following discussion is based upon economic and financial information contained in the *Rosemont Copper Project Updated Feasibility Study* (M3 Engineering and Technology Corp.). All dollar-denominated figures in this report are stated in terms of 2008\$ to be consistent with the cost/financial data in the feasibility study.

The total cost of construction is estimated to be \$897 million. The cost figures for the construction and development of the site for mining as reported in the feasibility study are summarized in Table 1. Expenditures for goods and services, payrolls, and tax payments associated with the engineering/construction phase will total \$881 million over a four-year period. Table 2 lists the total and yearly expenditures for the engineering/construction phase.

The productive life of the Rosemont Copper Project is projected to be 20+ years. Based on the cost analysis presented in the updated feasibility study, the total costs associated with the production/post-production phase of the Project, including reclamation and costs related to closure of the mine will total over \$6 billion. Table 3 summarizes the cost figures for a representative year during the production phase as reported in the feasibility study. The total cost figure translates to \$5.1 billion in expenditures for goods and services, payrolls, and government payments -- or approximately \$252 million per year over the 20-year production period. Table 2 lists the total and yearly expenditures during the production/post-production phase of the Project. These figures include spending associated with the mining operations, processing of the ore, maintenance/replacement of facilities and equipment, reclamation, administration, taxes, and other outlays, but do not include accounting cost components such as salvage value and depreciation.

3. Economic Impacts

Economic impacts are measured as changes in economic activity attributable to an event or policy change. Economists distinguish between direct impacts and total impacts. The direct impacts are changes in the economy that are the direct result of the event or policy change. In this study, the event being analyzed is the Rosemont Copper Project and the direct impacts of the construction and operation of the Project will be the purchases of goods and services from suppliers, the wages and salaries paid to mine employees, and the taxes and other payments to governments. The total impacts of the Project will be the final changes in the area economy after all of the indirect effects caused by the direct impacts have worked their way through the economy. Conventionally, the total impacts are measured by the additional economic activity that occurs as a result of the event or policy change – in terms of economic measures such as output, income, employment, etc.

The estimates of the direct impacts and of the total impacts have been produced by very different methods. The direct impacts have been calculated from information in the *Rosemont Copper Project Updated Feasibility Study* in combination with other data from secondary sources. The total economic impacts of the Rosemont Copper Project were estimated using three different versions of the REMI PI+ regional economic forecasting model. These computer models were developed by Regional Economic Models Inc. for use by a consortium of Arizona state agencies, including Arizona State University. The estimates of the direct impacts were used as inputs to the process, and the REMI models generated detailed estimates of the total economic impacts. The methodology and data used to develop the estimates of the direct impacts and the operation of the REMI PI+ model are described in the Technical Appendix.

The economic impacts for the Cochise/Pima/Santa Cruz Counties study area were estimated using a county-level version of the Arizona-specific REMI PI+ model. The economic impacts of the Project for the State of Arizona were estimated using a state-level version of the model, and the impacts for the U.S. economy were estimated using a national version of the REMI PI+ model.

3.1 Direct Impacts

3.1.1 Engineering/Construction Phase

Total spending associated with the engineering/construction phase will be \$881 million. However, much of the equipment and specialized services to be purchased is not produced within the three-county study area or the State of Arizona. The total expenditures for goods and services from local suppliers in Cochise/Pima/Santa Cruz Counties (including the local share of the value of equipment ordered through local suppliers but produced elsewhere) are estimated at \$205 million. Annual spending levels over the four-year engineering/construction period in the three-county study area are shown in Table 4. Most of these expenditures would be focused in the construction, mining support, and business services sectors.

At the statewide level, total purchases of goods and services from Arizona suppliers would be slightly higher at \$221 million. Annual expenditures in Arizona for the four-year engineering/construction period are listed in Table 5. Again, most of these expenditures would occur in the construction, mining support, and business services sectors.

3.1.2 Production/Post-Production Phase

Total direct spending associated with the production/post-production phase (including reclamation and mine closure activities) will be more than \$5.1 billion over a 25-year period. These expenditures will produce the following direct economic impacts within the Cochise/Pima/Santa Cruz Counties study area: \$1.5 billion in purchases of goods and services from local suppliers (shown as non-labor expenditures); an average of 406 jobs and \$438 million in wages and salaries paid to area workers; and \$132 million in revenues to local area governments. The annual figures for each of these measures are shown in Table 4.

The direct economic impacts of the production/post-production phase for the State of Arizona will produce substantially larger amounts of purchases of goods and services from Arizona

suppliers – \$1.9 billion – and \$225 million in state government revenues. The annual figures for the direct impacts for the State of Arizona are shown in Table 5.

3.2 Total Impacts

This section summarizes the results from the REMI model. The total impacts of the Project are measured in terms of:

- Output The dollar value of all goods and services produced in the region.
- Gross Regional Product The dollar value of all goods and services produced for final demand in the region. It excludes the value of intermediate goods and services purchased as inputs to final production.
- Personal Income The total income received by residents of the region from all sources.
- Total Employment the number of full- and part-time jobs by place of work.
- Government Revenues taxes and other payments received by the region's government(s).

3.2.1 Engineering/Construction Phase

3.2.1.A Cochise/Pima/Santa Cruz Counties

The development of the Rosemont Copper Project site over four-year engineering/construction period will produce substantial benefits for the Cochise/Pima/Santa Cruz Counties study area. It will generate an average annual increase of \$96 million in economic activity in the area (measured in terms of demand for goods and services from local suppliers) and will provide a total of 3,600 person-years of employment for local workers. The wages and salaries and non-labor income (dividends, interest, rent, proprietors' income and net profits) produced by the economic activity will provide an average of \$38 million per year in additional income to area residents and \$5 million per year in incremental revenues to local governments in the region. Over the entire engineering/construction period, these impacts are equivalent to \$385 million in additional demand for goods and services from local suppliers,

\$245 million in gross regional product, \$152 million in personal income, and \$18 million in local government revenues (Table 6).

The economic impacts of the engineering/construction phase of the Rosemont Copper Project will not be confined to the study area's mining and construction industries. The overall economic impacts (taking into account the combination of the direct and indirect effects) will be felt across all sectors of its economy. The strongest impacts will be on the construction, manufacturing, trade, business services, and health/social assistance sectors. Appendix tables A1, A2, and A3 show the incremental private-sector economic activity in each of 19 major industries in terms of output, employment, and earnings respectively.

3.2.1.B The State of Arizona

The development of the Rosemont Copper Project site will produce even larger benefits for the State of Arizona. It will generate an average annual increase of \$122 million in economic activity in the state (measured in terms of demand for goods and services from Arizona suppliers) and will provide a total of 3,900 person-years of employment for Arizona workers. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$45 million per year in additional income to state residents and \$6 million per year in incremental state government revenues. Over the entire engineering/construction period, these impacts are equivalent to \$489 million in additional demand for goods and services from Arizona suppliers, \$317 million in gross regional product, \$182 million in personal income, and \$23 million in state government revenues (Table 7).

The economic impacts of the engineering/construction phase of the Rosemont Copper Project will not be confined to Arizona's mining and construction industries. The overall economic impacts (accounting for both the direct and indirect effects) will be felt across all sectors of its economy. The strongest impacts would be on the construction, manufacturing, trade, and business services sectors. Appendix tables A4, A5, and A6 list the incremental private-sector economic activity in each of 19 major industries in terms of output, employment, and earnings respectively.

Table 6: Rosemont Copper Project - Engineering/Construction Phase - Total Impacts by Year Cochise/Pima/Santa Cruz Counties Study Area

(Millions 2008\$)

	Output	Gross Regional Product	Personal Income	Employment	Local Government Revenues

PP1	263.8	169.4	93.1	2,086	12.5
Production Phase					
1	49.9	34.7	27.7	388	2.2

Output is the dollar value of all goods and services produced in the region, including intermediate goods as well and value added (compensation and profit).

Gross regional product is the dollar value of all goods and services produced for final demands. It excludes intermediate goods and services.

Personal income is the total income received by residents from all sources.

Columns may not add due to rounding.

^{*} Total figure for employment is measured in terms of person-years of employment.

3.2.1.C The United States

The development of the Rosemont Copper Project site will also produce substantial benefits to the national economy. It will generate an average annual increase of \$568 million in economic activity (measured in terms of demand for goods and services from U.S. suppliers) and will provide a total of 11,600 person-years of employment for U.S. workers. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$167 million per year in additional income to U.S. residents and \$53 million per year in incremental revenues to the federal government. Over the entire engineering/construction period, these impacts are equivalent to \$2.3 billion in additional demand for goods and services, \$1.2 billion in gross domestic product, \$668 million in personal income, and \$210 million in federal government revenues (Table 8).

The overall economic impacts (taking into account the combination of the direct and indirect effects) will be distributed broadly across all sectors of the U.S. economy. The strongest impacts would be on the manufacturing, trade, and business services sectors. Appendix tables A7, A8, and A9 show the incremental private-sector economic activity in each of 19 major industries in terms of output, employment, and earnings respectively.

3.2.2 Production/Post-Production Phase

The economic benefits associated with the operation of the Rosemont Mine will be much larger in scale than those generated by its construction for all three levels of geography.

3.2.2.A Cochise/Pima/Santa Cruz Counties

Production activities will generate an average annual increase of \$701 million in economic activity (measured in terms of incremental regional output) within the three-county study area and will provide an average of 2,100 jobs for area residents. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$143 million per

^{*} Total figure for employment is measured in terms of person-years of employment.

year in additional income to area residents and \$19 million per year in incremental revenues to local governments in the study area. (All measured over the 20-year production period.) Over the entire production/post-production period, these impacts are equivalent to \$15 billion in additional output, \$8 billion in gross regional product, \$3 billion in personal income, and \$404 million in local government revenues (Table 9).

The economic impacts of the production/post-production phase of the Rosemont Copper Project will not be confined to the mining industry. The overall economic impacts (taking into account both the direct and indirect effects) will be felt across all sectors of the study area's economy. The strongest impacts would be on the mining, utility, manufacturing, trade, real estate/rental/leasing, and business services sectors. Appendix tables A10, A11, and A12 show the incremental private-sector economic activity in each of 19 major industries in terms of output, employment, and earnings respectively.

3.2.2.B The State of Arizona

Production activities will generate an average annual increase of \$907 million in economic activity (measured in terms of incremental output) within the State of Arizona and will provide an average of 2,900 jobs for state residents. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$218 million per year in additional income to state residents and \$32 million per year in incremental state government revenues. (All measured over the 20-year production period.) Over the entire production/post-production period, these impacts are equivalent to \$19 billion in additional output, \$11 billion in gross regional product, \$5 billion in personal income, and \$681 million in state government revenues (Table 10).

The economic impacts of the production/post-production phase of the Rosemont Copper Project will not be confined to the state's mining industry. The overall economic impacts (taking into account the combination of direct and indirect effects) will be widely distributed across all sectors of the Arizona economy. The strongest impacts would be on the mining, utility, construction, manufacturing, trade, real estate/rental/leasing, and business services sectors.

Columns may not add due to rounding.

Gross regional product is the dollar value of all goods and services produced for final demands. It excludes intermediate goods and services.

^{*}Annual average values refer to years 1 - 20 when full production activity will occur.

Appendix tables A13, A14, and A15 present the incremental private-sector economic activity in each of 19 major industries in terms of output, employment, and earnings respectively.

3.2.2.C The United States

Production activities will generate an average annual increase of \$1.3 billion in economic activity for the nation and will provide an average of 4,500 jobs for U.S. residents. The wages and salaries and non-labor income produced by the economic activity will provide an average of \$387 million per year in additional income to U.S. residents and \$128 million per year in incremental revenues for the federal government. (All measured over the 20-year production period.) Over the entire production/post-production period, these impacts are equivalent to \$27 billion in additional output, \$15 billion in gross domestic product, \$8 billion in personal income, and \$3 billion in federal government revenues (Table 11).

The overall economic impacts (accounting for both the direct and indirect effects) will be widely distributed across all sectors of the U.S. economy. The strongest impacts would be on the utility, manufacturing, trade, finance/insurance, and business services sectors. Appendix tables A16, A17, and A18 show the incremental private-sector economic activity in each of 19 major industries in terms of output, employment, and earnings respectively.

4. Concluding Observations

4.1 Population Changes

Unlike most other regional economic impact models, REMI is a dynamic model that produces integrated multiyear forecasts and accounts for dynamic feedbacks among its economic and demographic variables. As such, it provides forecasts of the demographic impacts of the development and operation of the Rosemont mine in addition to forecasts of economic variables.

Output is the dollar value of all goods and services produced in the region, including intermediate goods as well as value added.

Personal income is the total income received by residents from all sources.

Columns may not add due to rounding.

Gross domestic product is the dollar value of all goods and services produced for final demands. It excludes intermediate goods and services.

^{*}Annual average values refer to years 1 - 20 when full production activity will occur.

The results of the analysis indicate that net migration into the Cochise/Pima/Santa Cruz Counties study area will increase by more than 300 per year in the early years of operation and then lessen, with an annual average net migration figure of about 150 over the entire 20-year production period. This increase in net migration would mean that the population of the study area would be approximately 2,000 larger after five years and more than 4,000 larger by the end of the production period compared with a situation in which the Rosemont Copper Project was not developed.

Similarly, the results of the state-level analysis indicate that net migration into Arizona will increase by more than 500 per year in the early years of operation and then lessen, with an annual average net migration figure of about 230 over the entire 20-year production period. This increase in net migration would mean that the state's population would be approximately 3,000 larger after five years and 7,000 larger by the end of the production period compared with a situation in which the Rosemont Copper Project had not been developed.

4.2 Residual Impacts

Results from the REMI forecasts of economic activity for the years after the closure of the mine show that the Rosemont Copper Project would have lasting effects on the economy of the three-county study area over and above the impacts during its 26-year "active" period. Permanent changes to the business community, to the labor market, to local governments, and to many other aspects of the local economy would occur as a result of the development and operations of the Rosemont mine. These changes will result in residual economic impacts in the Cochise/Pima/Santa Cruz Counties area. The forecast results indicate that the level of economic activity would be \$52 million per year higher, area residents' income \$68 million per year higher, employment more than 300 higher, and local government revenues \$2 million per year higher than if the Rosemont Copper Project had never existed. Annual figures for each of these measures for the ten years after closure are listed in Table 12.

The REMI state-level forecast for years after the closure of the mine show that the Rosemont Copper Project would also have similar lasting effects on the Arizona economy. Permanent

^{*}Total figures refer to the sum of years 24-33. Residual impacts would continue after year 33.

changes to the business community, to the labor market, to the state government, and to many other aspects of the Arizona economy would occur as a result of economic activity induced by the development and operation of the Rosemont mine, and these changes would result in residual economic impacts within Arizona. The state-level forecast results indicate that the level of economic activity would be \$111 million per year higher, the state residents' income \$96 million per year greater, employment 500 higher, and state government revenues \$4 million per year higher than if the Rosemont Copper Project had never existed. Annual figures for each of these measures for the ten years after the end of operations are provided in Table 13.

Results from the REMI national forecast do not show similar lasting effects for the overall U.S. economy.

Table 13: Rosemont Copper Project - Residual Impacts by Year State of Arizona

(Millions 2008\$)

		Gross			State

Output is the dollar value of all goods and services produced in the region, including intermediate goods as well and value added (compensation and profit).

Personal income is the total income received by residents from all sources.

Columns may not add due to rounding.

Gross regional product is the dollar value of all goods and services produced for final demands. It excludes intermediate goods and services.

^{*}Total figures refer to the sum of years 24-33. Residual impacts would continue after year 33.

TECHNICAL APPENDIX

A1. Economic Impact Analysis Using the REMI Model

This study used the REMI PI+ regional forecasting model to produce numeric estimates of the economic impacts associated with the construction, operation, and closure of the Rosemont mine. The general method for estimating impacts using the REMI model involves 4 steps:

- Preparation of a baseline or control forecast for the study area this baseline scenario
 provides a forecast of the future path of the study area's economy based on a
 combination of the extrapolation of current economic conditions and an exogenous
 forecast of relevant economic variables without any changes in public policy or other
 external factors.
- 2. Development of a policy scenario this policy scenario describes the direct effects that the event(s) in this case the construction, operation, and closure of the Rosemont mine would have on the study area's economy.
- 3. Preparation of a forecast simulation of the area economy based on the policy scenario this alternative forecast provides a forecast of the future path of the area economy incorporating the effects of the changes specified in the policy scenario.
- 4. Comparison of the baseline and policy scenario forecasts the differences between the future values of each variable in the forecasts provide numeric estimates of the nature and magnitudes of the economic impacts of Rosemont Copper Project on the study area.

A2. The REMI Model

REMI is an economic-demographic forecasting and simulation model developed by Regional Economic Models Inc. REMI is designed to forecast the impact of public policies and external events on an economy and its population. The REMI model is recognized by the business and academic community as the leading regional forecast/simulation tool available. A complete explanation of the model and discussion of the empirical estimation of the parameters/equations are given in *Regional Economic Modeling: A Systematic Approach to*

Economic Forecasting and Policy Analysis (Treyz), Policy Insight 9.5: Model Documentation (REMI), Introduction to PI+: The Next Generation of Policy Insight (REMI), and PI+: Changes from Policy Insight v9.5 (REMI).

The REMI models used for this analysis were all versions of Policy Insight Model PI+ Version 1.1 leased from Regional Economic Models Inc. by a consortium of State agencies, including Arizona State University, for economic forecasting and policy analysis.

A3. Updating of the Baseline or Control Forecast

The PI+ v 1.1 models were delivered with national and local datasets containing data through 2007 and also with national and local baseline forecasts prepared by Regional Economic Models Inc. The REMI model incorporates procedures for updating the datasets and the baseline forecasts with more recent data. The research team performed these procedures to prepare updated baseline forecasts for this study. In practice, the methodology requires first updating the national baseline forecast since forecast values of national economic variables are important inputs to the state-level and county-level forecasts.

The national forecast was updated by using 2008 data from the U.S. Bureau of Economic Analysis and forecast data for the 2009–2017 period from the latest available Global Insight national forecast (September 2009). The baseline forecast of the Arizona model was updated based on 2008 employment data from the Arizona Department of Commerce.

A4. Definition of the Local Study Area

REMI is a county-based model, so that the study area must be defined in terms of one or more Arizona counties. The site on which the Rosemont Copper Project is being developed is located in Pima County southeast of the Tucson urbanized area, near the border with Santa Cruz County, and also in relatively close proximity to Cochise County. The approved bounds of analysis for the environment impact assessment have been defined by the U.S. Forest Service to include three counties – Cochise, Pima, and Santa Cruz Counties. Based on this definition, the

combined three-county region was specified as the study area for the county-level REMI economic impact analysis.

A5. Definition of the Study Period

REMI is a dynamic model that produces integrated multiyear forecasts. The analysis of the economic impacts of the Rosemont Copper Project has employed this feature of the model. The feasibility study provides annual information relating to both capital and operating costs for the projected lifetime of the Project. The timeline for the Project in the study includes three preproduction years (designated years PP3 through PP1 in this report), a production period of 20 years (designated years 1 through 20), and a post-production period of three years (years 21 through 23). The first year of the post-production period (Year 21) includes some production activity during the first part of the year. The economic impact analysis of the construction phase provides estimates of the impacts over the four-year engineering/construction period specified in the feasibility study (year PP3 to year 1). The analysis of the production/post-production phase encompasses a 25-year period (years PP2 through year 23).

The REMI model requires specification of calendar year time periods for its forecast process. Based on a timeline on the Rosemont Copper Project website, the study period starting date (PP3) was assumed to be 2009.

A6. Calculation of the Direct Impacts

All of the estimates of the direct impacts of the Rosemont Copper Project were based on the economic and financial information contained in the *Rosemont Copper Project Updated Feasibility Study* (M3 Engineering and Technology Corp.). Information from two other reports relating to the Rosemont Copper Project was also used to supplement the information in the feasibility study:

- Data relating to reclamation costs from the *Mined Land Reclamation Plan* (Tetra Tech Inc).
- Information relating to various aspects of construction and operation from the *Mine Plan of Operations* (WestLand Resources Inc).

The REMI model requires input data in very specific formats. In particular, the data must conform to the 70 economic sectors in the model. In many cases the economic data provided by the feasibility study and the other two reports were not sufficiently detailed to be used directly as inputs for the REMI model. Detailed data from the direct requirements table in the *U.S. Benchmark Input-Output Accounts* (U. S. Bureau of Economic Analysis) were used to convert the information into a form usable by the model. The direct requirements coefficients for each industry specify the dollar amount of inputs from each supplying industry needed to produce a dollar of industry output.

A7. Government Revenues

Estimates of revenues received by each of the three levels of government from Rosemont Copper operations were based on tax information contained in the *Rosemont Copper Project Updated Feasibility Study*. The share of state transactions privilege tax, severance tax, and income tax collections distributed to the area local governments was calculated from data in the Arizona Department of Revenue *FY2008 Annual Report*.

Estimates of revenues received by area local governments and the state government as a result of the incremental economic activity induced by Rosemont Copper operations and/or construction activities were based on ratios of collections per dollar of gross regional product calculated from data obtained from the U.S. Census Bureau's *State and Local Government Finances database*. Estimates of revenues received by the federal government as a result of the incremental economic activity induced by Rosemont Copper operations and/or construction activities were based on ratios of collections per dollar of gross domestic product calculated from data obtained from the U.S. Census Bureau's 2009 *Statistical Abstract*.

A8. Inconsistencies in the Results across the Three Regions

The economic impacts for the Cochise/Pima/Santa Cruz Counties study area were estimated using a county-level version of the Arizona-specific REMI PI+ model. The economic impacts of the Project for the State of Arizona were estimated using a state-level version of the model, and the impacts for the U.S. economy were estimated using a national version of the REMI PI+ model. The three sets of economic impact estimates were based on the same input data relating to the direct impacts of the construction and operation of the Mine, but were calculated independently using the three different versions of the REMI PI+ model.

Logically, the magnitude of the economic impacts of the Rosemont Copper Project with respect to the three-county study area should have been smaller than the impacts on the Arizona economy, because at least some of the activity associated with the Project would be expected to affect the economies of Arizona communities outside the study area – particularly the Metro Phoenix area. Similarly, the magnitude of the Project's impacts on the Arizona economy should have been smaller than the impacts measured for the U. S. economy, since many of the goods and services needed for the construction and operation of the Rosemont Mine would be supplied by economic agents located outside Arizona. Comparison of equivalent economic measures across the three levels of geography shows that this was true in most cases. In a few specific instances, however, the estimated values of the economic impacts across the three geographic levels were not consistent. This situation is due to a combination of two factors:

1. While the structures of the county-level model and state-level model are similar, the equations in the models that specify the relationships between the economic variables were based on different sets of data. The equations in the county-level model were developed based upon county-specific data. The state-level model was developed using state-level information. In general, less economic data are available at the county level than for states, and the county level data are often subject to larger margins of error – this is particularly true for smaller counties, such as two of the three counties in the study area. The numbers produced by the REMI model are "point estimates" of the magnitudes of the economic impacts of the event being evaluated. As with all statistical models based on economic data that are subject to measurement error, the estimates/forecasts produced by such models also have margins of error. Given the relative quality of the data used to develop the county-level versus state-level models, the estimates produced by the county-level model can be expected to have larger margins of error.

Factor #1 also applies in the comparison of county and state models versus national models. Information relating to the national economy is much more prevalent and generally of higher quality than sub-national data. In addition, there is another factor leading to inconsistencies between the U. S. numbers and the county and state results.

2. The U. S. numbers in the report were produced using a national version of the REMI PI+ model that is included as part of the county/state models. Although it can be used to evaluate the national level economic impact of events such as the construction/operation of the Rosemont Mine, it was primarily included in the state-level model to allow researchers to develop alternative national forecasts as inputs to the state model. As such, the structure is somewhat different that the county/state-level models used to produce the other two sets of estimates. These differences meant that (a) the input data specifying the direct impacts of the Rosemont Copper Project had to be reformulated for use in the national model, and (b) the format of results produced by the national model was somewhat different and not as detailed as that in the county/state level models.
